ATLAS Z-Path Masterclass 2017
It’s a time of exciting new discoveries in particle physics!

At CERN, the LHC successfully completed Run I at 8 TeV of collision energy, confirming that the measurements correspond well to the Standard Model and then finding the Higgs boson. The LHC is now into Run II at an amazing 13 TeV and the task is to look for new phenomena…and we are off to a great start.
The LHC is buried ~100 m below the surface near the Swiss-French border.

beams accelerated in large rings (27 km circumference at CERN)
Generic Design
Cylinders wrapped around the beam pipe
From inner to outer . . .

Tracking
Electromagnetic calorimeter
Hadronic calorimeter
Magnet*
Muon chamber

*Location of magnet depends on specific detector design.
ATLAS Detector

Play with ATLAS online!
If each beam proton has energy 4 TeV...

• The total collision energy is $2 \times 4 \text{ TeV} = 8 \text{ TeV}$.
• But each particle inside a proton shares only a portion.
• So a newly created particle’s mass **must be** smaller than the total energy.
The collisions create new particles that promptly decay. Decaying particles *always* produce lighter particles.

Conservation laws allow us to see patterns in the decays.

Can you name some of these conservation laws?
Often, quarks are scattered in collisions.

As they separate, the binding energy between them converts to sprays of new particles called jets. Also, lower energy electrons and muons can emerge.

They are not what we are looking for.
We are looking for the Z boson, a particle with no charge that decays into two muons or two electrons.*

What do we know about the charges of the muons or electrons? What is the charge of the Z?

*The Z has other decays . . . but these are not what we are looking for.
A “dimuon” or “dielectron” event *might* be a decay of the particle that we are interested in.

It may be hard to find the tracks we want unless we make a “cut” on low-energy tracks.
If we cut out all tracks below, say, 5 GeV momentum, the picture is clearer.

Today, we will filter many events to find $Z \rightarrow e^+ e^-$ and $Z \rightarrow \mu^+ \mu^-$ signals and use momentum information from these to find the mass of the Z boson.
The Higgs boson was discovered by CMS and ATLAS and announced on July 4, 2012.

This long-sought particle is part of the “Higgs mechanism” that accounts for other particle having mass.
How are these events similar? Different? Why?
How are these events similar? Different? Why?
How are these events similar? Different? Why?

“Science is nothing but developed perception, interpreted intent, common sense rounded out and minutely articulated.” George Santayana

- Indirect observations and imaginative, critical, logical thinking can lead to reliable and valid inferences.

- Therefore: **work together, think** (sometimes outside the box), and **be critical** of each other’s results to figure out what is happening.
Let’s Analyze Events!

Make teams of two.
Practice.
Talk with physicists.
Find good Z and H candidates…and more.
Which events will be included in the mass plot?
AND plot the mass!
Report! Rapport! Rejoice! Relax!
